

Mid-term Status Update

Mert Ahmet Ayyildiz

01125172

Implementation:

I have so decide that for MS-1 authentication service with PHP Application logic for implementation. I also downloaded with SLIM Framework. It's easy to learn and use (it's great for routing). As server I currently use Wampserver (wamp64) and for the database Mysql. HTTP protocol was used for the application layer.

Service Deployment:

The service is currently only running on my computer with wampserver (localhost).

Authentication:

if we give our data (name and password) then we should get back a Json file back, for example {"name":mert, "password":12377}.

Testing and Presentation:

I tested my implementation with app Postman (with just Get and Post methods) and with my browser. I can get Json String back.

Now up to date and What will come:

Slim Framework, Twig and Vendor downloaded. Next to it Controller and HomeController (main) has been created. With var_dump I'll pull out of that json string. Bootstrap especially

includes my database properties and much. In public folder there is css-2018. It's my visual codes inside. It is not written by itself but found by Internet to try. At the end it will be deleted. I have some news block as we can write our data (email, name, password). Next step Finish database and send json to another.

Its requirements

and works as expected, even if your team colleagues failed to implement their services.

Think about suitable ways to present the functionality of your service.
